

Stator Bobbins for Axial Winding

Background of the Invention

1. Field of the Invention

The present invention relates to stator bobbins for axial winding.

2. Description of the Related Art

A conventional motor structure of fan includes a stator bobbin. As illustrated in Fig. 1 of the drawings, the conventional stator bobbin 90 comprises an upper pole plate 91, a lower pole plate 92, and an axle tube 93 mounted thereto. A space 94 is formed around a central hole of the stator bobbin 90 for receiving a winding 95. A shaft of a rotor 96 is rotatably mounted in the axle tube 93. A motor is thus constructed. The poles of the upper and lower pole plates 91 and 92 cooperate with a ring magnet 97 attached to the rotor 96. Since the winding 95 is uniformly distributed along the radial direction and since the magnetic flux is in proportion to the number of the turns of the winding, the number of the turns must be increased when it is desired to generate a larger magnetic flux. As a result, the height or diameter of the stator bobbin as well as the length of the winding must be increased in order to obtain a gain in the motor output torque for the purpose of increasing the output power of the motor.

Summary of the Invention

It is an object of the present invention to provide a motor stator bobbin including a first disc, a second disc, and a connecting tube that connects the first disc with the second disc. During formation of the winding, most of the winding is densely wound around the connecting tube in a manner that the turns adjacent to the connecting tube is denser such that a larger magnetic flux is generated when electricity is applied. Thus, the motor output torque is increased without adversely affecting the winding procedure of the motor.

In an embodiment of the invention, a stator bobbin for axial winding is made from insulating material and includes a first disc, a second disc, and a connecting tube that connects the first disc with the second disc. The connecting tube has a central hole and a space for winding is defined between the first disc and the second disc. A first pole plate is attached to

1 an outer side of the first disc and a second pole plate is attached to an outer side of the second
2 disc. A distance between an outer end of the inner side of the first disc and an outer end of the
3 inner side of the second disc is greater than that between an inner end of the inner side of the
4 first disc and an inner end of the inner side of the second disc.

5 Other objects, specific advantages, and novel features of the invention will become
6 more apparent from the following detailed description and preferable embodiments when
7 taken in conjunction with the accompanying drawings.

8 **Brief Description of the Drawings**

10 Fig. 2 is an exploded perspective view of a first embodiment of a stator bobbin in
11 accordance with the present invention.

12 Fig. 3 is a sectional view of the stator bobbin in Fig. 2.

13 Fig. 4 is a sectional view of a second embodiment of the stator bobbin in accordance
14 with the present invention.

15 Fig. 5 is a sectional view of a third embodiment of the stator bobbin in accordance with
16 the present invention.

17 Fig. 6 is a sectional view of a fourth embodiment of the stator bobbin in accordance
18 with the present invention.

19 **Detailed Description of the Preferred Embodiments**

20 Preferred embodiments in accordance with the present invention will now be described
21 with reference to the accompanying drawings.

22 Referring to Fig. 2, a first embodiment of a stator bobbin 1 for axial winding in
23 accordance with the present invention is made from insulating material (preferably plastics)
24 and includes a first disc 11, a second disc 12, and a connecting tube 13 that connects the first
25 disc 11 with the second disc 12. The connecting tube 13 has a central hole 14. A space 15 for
26 winding is defined between the first disc 11 and the second disc 12. It is noted that an inner
27 side of the first disc 11 and an inner side of the second disc 12 are not parallel to each other. In

1 this embodiment, at least one of an inner end of the inner side of the first disc 11 and an inner
2 end of the inner side of the second disc 12 has an inclined section 16 to thereby form a
3 narrower section in the space 15 for winding. As a result, the distance between an outer end of
4 the inner side of the first disc 11 and an outer end of the inner side of the second disc 12 is
5 greater than that between an inner end of the inner side of the first disc 12 and an inner end of
6 the inner side of the second disc 12.

7 A first pole plate 2 is attached to an outer side of the first disc 11 and a second pole plate
8 3 is attached to an outer side of the second disc 12. The pole plates 2 and 3 can be of any
9 conventional shapes and structures. Each pole plate 2, 3 has poles 21, 31 for induction with a
10 permanent magnet (not shown) on a rotor (not shown) for driving the rotor, which is
11 conventional and therefore not described in detail.

12 Fig. 3 illustrates the stator bobbin in an assembled state in which a winding 4 is wound
13 in the space 15 of the stator bobbin 1. During formation of the winding 4 by means of winding
14 wires reciprocatingly around the connecting tube 13, since a narrower section is defined in an
15 inner end of the space 15 by the inclined sections 16 respectively formed on the inner ends of
16 the inner sides of the first and second discs 11 and 12, the wires for forming the winding 4 will
17 slide toward the connecting tube 13 when winding around the inclined sections 16. Thus, the
18 winding 4 is denser in an area of the space 15 that is adjacent to the connecting tube 13. After
19 the winding procedure, it is appreciated that the winding 4 wound around the connecting tube
20 13 at a place proximal to the connecting tube 13 is distributed in a manner denser than that
21 wound around the connecting tube 13 at a place distal to the connecting tube 13. Thus, the
22 stator bobbin 1 generates a larger magnetic flux after electricity is applied, thereby providing a
23 gain in the motor output torque.

24 Fig. 4 illustrates a second embodiment of the stator bobbin 1 in accordance with the
25 present invention. The stator bobbin 1 also includes a first disc 11, a second disc 12, and a
26 connecting tube 13 that connects the first disc 11 with the second disc 12. The connecting tube
27 13 has a central hole 14. A first pole plate 2 is attached to an outer side of the first disc 11 and

1 a second pole plate 3 is attached to an outer side of the second disc 12. A space 15 for winding
2 is defined between the first disc 11 and the second disc 12. It is noted that at least one of an
3 inner side of the first disc 11 and an inner side of the second disc 12 extends in a direction that
4 is not perpendicular to a longitudinal axis of the central hole 14 of the connecting tube 13. In
5 this embodiment, each of the inner side of the first disc 11 and the inner side of the second
6 disc 12 is an inclined surface 16 to thereby form a space 15 that tapers radially inward. As a
7 result, the distance between an outer end of the inner side of the first disc 11 and an outer end
8 of the inner side of the second disc 12 is greater than that between an inner end of the inner
9 side of the first disc 12 and an inner end of the inner side of the second disc 12. During
10 formation of the winding 4 by means of winding wires reciprocatingly around the connecting
11 tube 13, since the space 15 tapers radially inward due to provision of the inclined surfaces 16,
12 the wires for forming the winding 4 will slide toward the connecting tube 13. Thus, the
13 winding 4 is denser in an area of the space 15 that is adjacent to the connecting tube 13. After
14 the winding procedure, it is appreciated that the winding 4 wound around the connecting tube
15 13 at a place proximal to the connecting tube 13 is distributed in a manner denser than that
16 wound around the connecting tube 13 at a place distal to the connecting tube 13. Thus, the
17 stator bobbin 1 generates a larger magnetic flux after electricity is applied, thereby providing a
18 gain in the motor output torque.

19 Fig. 5 illustrates a third embodiment of the stator bobbin 1 in accordance with the
20 present invention. The stator bobbin 1 also includes a first disc 11, a second disc 12, and a
21 connecting tube 13 that connects the first disc 11 with the second disc 12. The connecting tube
22 13 has a central hole 14. A first pole plate 2 is attached to an outer side of the first disc 11 and
23 a second pole plate 3 is attached to an outer side of the second disc 12. A space 15 for winding
24 is defined between the first disc 11 and the second disc 12. It is noted that at least one of an
25 inner side of the first disc 11 and an inner side of the second disc 12 includes a number of
26 sections having different slopes. In this embodiment, each of the inner side of the first disc 11
27 and the inner side of the second disc 12 includes at least two stepped sections 17 and a

1 connecting section 18 between each two adjacent stepped sections 17. The stepped sections 17
2 are horizontal (namely, the stepped sections 17 extend in a direction perpendicular to a
3 longitudinal axis of the central hole 14 of the connecting tube 13) and located at different
4 levers. The connecting section 18 between the stepped sections 17 is an inclined surface or
5 arcuate surface. As a result, the distance between an outer end of the inner side of the first disc
6 11 and an outer end of the inner side of the second disc 12 is greater than that between an
7 inner end of the inner side of the first disc 12 and an inner end of the inner side of the second
8 disc 12. During formation of the winding 4 by means of winding wires reciprocatingly around
9 the connecting tube 13, the wires are firstly wound between the inner stepped sections 17, the
10 connecting sections 18, and then the outer stepped sections 17. Thus, the winding 4 is denser
11 in an area of the space 15 that is adjacent to the connecting tube 13. After the winding
12 procedure, it is appreciated that the winding 4 wound around the connecting tube 13 at a place
13 proximal to the connecting tube 13 is distributed in a manner denser than that wound around
14 the connecting tube 13 at a place distal to the connecting tube 13. Thus, the stator bobbin 1
15 generates a larger magnetic flux after electricity is applied, thereby providing a gain in the
16 motor output torque.

17 Fig. 6 illustrates a fourth embodiment of the stator bobbin 1 in accordance with the
18 present invention. The stator bobbin 1 also includes a first disc 11, a second disc 12, and a
19 connecting tube 13 that connects the first disc 11 with the second disc 12. The connecting tube
20 13 has a central hole 14. A first pole plate 2 is attached to an outer side of the first disc 11 and
21 a second pole plate 3 is attached to an outer side of the second disc 12. A space 15 for winding
22 is defined between the first disc 11 and the second disc 12. It is noted that at least one of an
23 inner side of the first disc 11 and an inner side of the second disc 12 includes a convex section
24 19 that is connected to the connecting tube 13. As a result, the distance between an outer end
25 of the inner side of the first disc 11 and an outer end of the inner side of the second disc 12 is
26 greater than that between an inner end of the inner side of the first disc 12 and an inner end of
27 the inner side of the second disc 12. During formation of the winding 4 by means of winding

1 wires reciprocatingly around the connecting tube 13, the wires for forming the winding 4 will
2 slide toward the connecting tube 13 due to provision of the convex sections 19. Thus, the
3 winding 4 is denser in an area of the space 15 that is adjacent to the connecting tube 13. After
4 the winding procedure, it is appreciated that the winding 4 wound around the connecting tube
5 13 at a place proximal to the connecting tube 13 is distributed in a manner denser than that
6 wound around the connecting tube 13 at a place distal to the connecting tube 13. Thus, the
7 stator bobbin 1 generates a larger magnetic flux after electricity is applied, thereby providing a
8 gain in the motor output torque.

9 According to the above description, it is appreciated that the distance between an outer
10 end of the inner side of the first disc 11 and an outer end of the inner side of the second disc 12
11 is greater than that between an inner end of the inner side of the first disc 12 and an inner end
12 of the inner side of the second disc 12 by means of providing non-parallel inner sides of the
13 first disc 11 and the second disc 12. Thus, when winding wires in the space 15 around the
14 connecting tube 13, the wires will be guided toward the connecting tube 13 by the inclined
15 sections or surfaces 16 or connecting sections 18 or convex sections 19. After the winding
16 procedure, the winding 4 wound around the connecting tube 13 at a place proximal to the
17 connecting tube 13 is distributed in a manner denser than that wound around the connecting
18 tube 13 at a place distal to the connecting tube 13. Thus, the stator bobbin 1 generates a larger
19 magnetic flux after electricity is applied, thereby providing a gain in the motor output torque
20 without adversely affecting the winding procedure for the motor.

21 Although the invention has been explained in relation to its preferred embodiment as
22 mentioned above, it is to be understood that many other possible modifications and variations
23 can be made without departing from the scope of the invention. It is, therefore, contemplated
24 that the appended claims will cover such modifications and variations that fall within the true
25 scope of the invention.
